Week 4

Character Theory

4.1 Representation Ring; Character Basis

• Announcements.

- – Reminder: Midterm 11/10.
- – OH this week in-person at normal times.
- – PSet 3 should be fun.

• Today: Finish proving some character things.

• Recall: The main picture.

- – Rudenko redraws Figure 3.1.
- – We have a finite group G and we are studying finite-dimensional G-reps over $\mathbb{C}$.
- – $\mathbb{C}_{\mathrm{cl}}[G]$ is a ring.
- – The map. . .
    - ■ Respects addition;
    - ■ Sends tensor multiplication to (pointwise) functional multiplication;
    - ■ Sends duality to conjugation;
    - ■ Respects a kind of inner product, whether it be either side of $\dim_{\mathbb{C}} \mathrm{Hom}_G(V, W) = \langle f_1, f_2 \rangle$.

• Today, we will see that $\mathbb{C}_{\mathrm{cl}}[G] \cong \mathbb{C}^k$, where k is the number of conjugacy classes.

- – In other words, we will see that the number of irreps is also exactly equal to k, that there is a bijection $\{V_i\} \to \{\chi_i\}$, and that the $\chi_1, \dots, \chi_k$ form an orthonormal basis of $\mathbb{C}_{\mathrm{cl}}[G]$.

• Visualizing the vector space $\mathbb{C}_{\mathrm{cl}}[G]$.

Figure 4.1: Visualizing the space of class functions on G.

- It's a "cone" emanating from the origin with only lattice points.
    - If $\dim \mathbb{C}_{\mathrm{cl}}[G] = 2$, the vector space consists of all the blue points in Figure 4.1.
- Why is it only lattice points instead of a continuous function space?
    - The restrictions on coefficients are inherited from the restrictions on what kinds of spaces you can build of the form $V_1^{n_1} \oplus V_2^{n_2}$.
    - Indeed, if it were continuous, that would imply that there is some meaning to the point $0.3\chi_1 + 2.5\chi_2$, i.e., there is a space $V_1^{0.3} \oplus V_2^{2.5}$. But of course, we cannot define such a space!
- Why is it only *nonnegative* integer coefficients and not *all* integer coefficients?
    - We don't have subtraction to get us to a full ring.
    - Additionally, we can only scale and linearly combine the χ_i's with nonnegative integer coefficients because, as said above, those are the types of reducible rep decompositions we have.

- Let $[V]$ denote the **isomorphism class** of the representation V.

- **Isomorphism class** (of V): The set of all vector spaces W that are isomorphic to V as representations.

- This allows us to define the **representation ring**.

- **Representation ring** (of G): The ring $(R, +, \cdot)$, where R is the free abelian group generated by all isomorphism classes of the representations of G, quotiented by the span of all linear combinations of the form $[V \oplus W] - [V] - [W]$; $+$ is well-defined via the construction of R, which yields $[V] + [W] = [V \oplus W]$ for all $[V], [W]$ in the ring; and $\cdot$ is defined by $[V] \cdot [W] = [V \otimes W]$. *Denoted by* $\boldsymbol{R(G)}$.

    - Basis: $[V_1], \ldots, [V_k]$.
    - Thus, structurally,
    $$R(G) \cong \mathbb{Z}^k$$
    - Elements are of the form $[V_1] + 2[V_2] - 3[V_3]$.
    - Multiplication is slightly complicated because $V_i \otimes V_j = \bigoplus V_k^{n_{ijk}}$; it follows that
    $$[V_i] \cdot [V_j] = \sum n_{ijk}[V_k]$$

- Alternative construction of $R(G)$: Take the subring of the class ring $\mathbb{C}_{\mathrm{cl}}[G]$ that is generated by the characters.

    - To do so, define a map $R(G) \to \mathbb{C}^k$ where the image is linear combinations of characters χ_i with $\mathbb{Z}$-class.
    - Clarify this construction??

- **Virtual representation**: An element of $R(G)$.

    - We need this term because some elements of $R(G)$ — like $-[V]$, for instance — may not correspond to an actual representation.
    - Indeed, note that $-[V]$ is *not* V^*; it is just some thing that when you add it to $[V]$, you get the zero representation.

- Example: Let $G = \mathbb{Z}/2\mathbb{Z} = \{e, x\}$.

    - Then $R(G) = \mathbb{Z}^2 = \mathbb{Z}e \oplus \mathbb{Z}x$ has basis $[1], [-1]$ (corresponding to the trivial and alternating representations) where we define
    $$[1]^2 = [1] \qquad\qquad [1][-1] = [-1] \qquad\qquad [-1]^2 = [1]$$

- One reason people like this $R(G)$ is as follows.

- Initially, understanding this group is not easy because even to get started, you have to find all your characters.
  - But, we know that
    $$R(G) \otimes_{\mathbb{Z}} \mathbb{C} \cong \mathbb{C}_{\mathrm{cl}}[G]$$
    - So we have a ring that's hard to understand, but if we do something called an **extension of scalars** (shown above) we get an easy ring!
    - Why?? Clarify this construction.[1]
  - This is interesting because we can look at the intermediate objects. For example, could we describe $R(G) \otimes \mathbb{R}$ or $R(G) \otimes \mathbb{Q}$. Interestingly, **Artin's theorem** describes $R(G) \otimes \mathbb{Q}$ completely.
  - If we try to understand $R(S_n)$, this is still hard work, but if we take $\bigoplus_{n \geq 0} R(S_n)$, we obtain an object that is remarkably, surprisingly simple. That's where we're going. This is why rep theory of finite groups is simultaneously very hard and very simple.

- Lemma: Let G be a finite group, let f be a complex-valued[2] class function, and let V be a G-rep. Then the linear map
  $$F = \sum_{g \in G} f(g) \cdot g : V \to V$$

  is a morphism of G-representations, that is, $F \in \mathrm{Hom}_G(V, V)$.

  Proof. To prove that $F \in \mathrm{Hom}_G(V, V)$, it will suffice to show that $xF = Fx$ for every $x \in G$. Let $x \in G$ be arbitrary. Then

  $$F(xv) = \sum_{g \in G} f(g) g x v$$

  Since ρ is a group homomorphism, the functions $\rho(g) \in GL(V)$ act just like the elements $g \in G$. *This* is what justifies us to basically move everything around all willy-nilly. Thus, continuing from the above, we have

  $$= \sum_{g \in G} f(g)(xx^{-1})gxv$$
  $$= \sum_{g \in G} f(g)x(x^{-1}gx)v$$

  Since $x = \rho(x)$ is in the general *linear* group, i.e., is a *linear* map, we can factor it out of the sum of functions to get

  $$= x \left(\sum_{g \in G} f(g)x^{-1}gx \right) v$$

  Since f is a class function by hypothesis, we have $f(g) = f(x^{-1}gx)$, so

  $$= x \left(\sum_{g \in G} f(x^{-1}gx)x^{-1}gxv \right)$$
  $$= x \sum_{g \in G} f(g)gv$$
  $$= x(Fv)$$

  as desired. $\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\square$

---

[1]See Week 9 OH (Section 9.3).
[2]This "complex-valued" hypothesis was not stated in class, but I have to imagine it's true. Is it??

- Recall that previously, we had $(1/|G|) \sum_{g \in G} g : V \to V^G$.

  - He will put something about this being a class function on the midterm?? Review how to prove that this is a class function!

- Another comment: A slightly refined question.

  - Suppose you have a class function f and an irrep V.
  - Then by the lemma, $F = \sum f(g)g : V \to V$ is a G-morphism.
  - Thus, it is a **homothety** by Schur's lemma, i.e.,

  $$\sum_{g \in G} f(g)\rho_V(g) = \lambda I_{d_V}$$

  where d_V denotes the **degree** of V.

    - It's basically tautological, but the following may help.
    - Note that we choose the d_V-dimensional identity matrix because $\rho_V(g)$ acts on V (which has $\dim V = d_V$), so we need the identity map that does the same.

  - Now, we will compute λ using the trace. Take the trace of both sides. Then

  $$\mathrm{tr}\left(\sum_{g \in G} f(g)\rho_V(g)\right) = \mathrm{tr}(\lambda I_{d_V})$$

  $$\sum f(g)\,\mathrm{tr}(\rho_V(g)) = \lambda d_V$$

  $$\sum f(g)\chi_V(g) = \lambda d_V$$

  $$\lambda = \frac{|G|}{d_V} \frac{1}{|G|} \sum_{g \in G} f(g)\overline{\chi_{V^*}(g)}$$

  $$= \frac{|G|}{d_V} \langle f, \chi_{V^*} \rangle$$

- **Homothety**: A map $F : V \to V$ for which there exists $\lambda \in \mathbb{C}$ such that $Fv = \lambda v$ for all $v \in V$.

  - It just means that we're scaling.

- **Degree** (of V): The dimension of V as a vector space. *Denoted by $\boldsymbol{d_V}$. Given by*

  $$d_V = \dim V$$

- Now, we can prove the theorem to which we've been building up the whole time.

- Theorem: Let G be a finite group. Then the number of irreps up to isomorphism is equal to the number of conjugacy classes.

  Proof. Let k be the number of conjugacy classes of G, and let $\chi_1, \ldots, \chi_s$ be the characters of the irreps. By the theorem from last Wednesday's class, it follows that $\chi_1, \ldots, \chi_s$ are orthonormal vectors in $\mathbb{C}_{\mathrm{cl}}[G]$. Thus, by the corollary to the aforementioned theorem, $s \leq k$.

  Now, suppose for the sake of contradiction that $s < k$. Then there exists a nonzero $f \in \mathbb{C}_{\mathrm{cl}}[G]$ such that $\langle f, \chi_{V_i} \rangle = 0$ $(i = 1, \ldots, s)$. By Gram-Schmidt, we can choose f to be another *orthonormal* vector in the list, extending it to $\chi_1, \ldots, \chi_s, f$. We will now build up to proving that $f(g) = 0$ for all $g \in G$ (i.e., $f = 0$), which we will do by using the above lemma to construct a linear independence argument as follows. The first step is to let V_i be an arbitrary irrep of G. Then by the above comment, $F : V_i \to V_i$ may be evaluated on any $v \in V_i$ as follows.

  $$F(v) = \lambda I v = \frac{|G|}{d_{V_i}} \langle f, \chi_{V_i^*} \rangle \cdot v = \frac{|G|}{d_{V_i}} \overline{\langle f, \chi_{V_i} \rangle} \cdot v = \frac{|G|}{d_{V_i}} \overline{0} \cdot v = 0$$

It follows that $F = 0$ on *any* representation since by complete reducibility, they're all direct sums of irreps. In particular, $F : V_{\text{reg}} \to V_{\text{reg}}$ is the zero operator, where $V_{\text{reg}} \cong V_1^{d_{V_1}} \oplus \cdots \oplus V_s^{d_{V_s}}$ is the regular representation. Thus, for example, $F(e_e) = 0$. But we also know that

$$F(e_e) = \sum_{g \in G} f(g) \cdot g e_e = \sum_{g \in G} f(g) \cdot e_g$$

Consequently, by transitivity, we have that

$$0 = \sum_{g \in G} f(g) \cdot e_g$$

But since the e_g are all linearly independent by the definition of the regular representation, we have that each $f(g) = 0$, as desired. This means that $f = 0$, contradicting our original supposition. $\square$

- That is the end of this story.

- Here's one consequence of the above theorem.

    - We now know that the space of class functions has an orthonormal basis $\chi_{V_1^*}, \ldots, \chi_{V_k^*}$.
    - If we denote the conjugacy classes of G by $C_1, \ldots, C_k$, then another obvious basis of $\mathbb{C}_{\text{cl}}[G]$ is $\delta_{C_1}, \ldots, \delta_{C_k}$ defined by

    $$\delta_{C_i}(g) = \begin{cases} 1 & g \in C_i \\ 0 & g \notin C_i \end{cases}$$

    - This new basis is orthogonal: We have

    $$\langle \delta_{C_i}, \delta_{C_j} \rangle = \frac{1}{|G|} \sum_{g \in G} \delta_{C_i}(g) \delta_{C_j}(g) = \begin{cases} 0 & i \neq j \\ \frac{|C_i|}{|G|} & i = j \end{cases}$$

        - Justifying this computation: If $i \neq j$, then at least one of $\delta_{C_i}, \delta_{C_j}$ will be zero; if $i = j$, then they're both nonzero and equal to 1 for all $|C_i|$ elements $g \in C_i$.
    - What is the change of basis matrix between $\{\delta_{C_i}\}$ and $\{\chi_{V_i^*}\}$? It's the character table.
        - The orthogonality condition for characters then just comes from the fact that we're going from one orthogonal basis to another.
        - What are the exact bases we change between??[3]

4.2   Office Hours

10/17:
- **Transitive** (group action): A group action for which the **orbit** of x is equal to X for any $x \in X$.

- **Orbit** (of $x \in X$): The set of $g \cdot x$ for all $g \in G$.

- **Diagonal action** (of G on $X \times X$): The action defined as follows. *Given by*

$$g \cdot (x_1, x_2) = (g \cdot x_1, g \cdot x_2)$$

- Check Etingof et al. (2011) for some things??

---

[3]See Week 9 OH (Section 9.3).

4.3   Orthogonality Results

10/18:
- Announcements.

    - Goal: Finish our discussion of the orthogonality of characters, projection functions, etc.
    - Friday: Frobenius determinant.
    - Next week: Group algebras, associative algebras, etc.; another perspective on representations.
    - After next week: A more advanced part of representation theory related to group theory.

- Describing Figure 3.1 from a different perspective.

    - Let G be a finite group, and let k denote the number of conjugacy classes and the number of irreps. Let $C_1, \ldots, C_k$ be the conjugacy classes and $V_1, \ldots, V_k$ be the irreps.
    - There is no natural/canonical bijection between the two sets. For a simple group, there is often a canonical way, and this is where things get interesting.

        ■ Example: Symmetric group induces canonical bijection, as we'll see later.

    - $\mathbb{C}_{\mathrm{cl}}[G] = \mathbb{C}^k$ is a vector space of class functions and a ring.
    - We have the Hermitian inner product

    $$\langle f_1, f_2 \rangle = \frac{1}{|G|} \sum_{g \in G} f_1(g)\overline{f_2(g)}$$

    - Recall that $\chi_{V_1}, \ldots, \chi_{V_k}$ is an orthonormal basis such that

    $$\langle \chi_{V_i}, \chi_{V_j} \rangle = \delta_{ij}$$

    - We have another basis $\delta_{C_1}, \ldots, \delta_{C_k}$ defined by

    $$\delta_{C_i}(g) = \begin{cases} 0 & g \notin C_i \\ 1 & g \in C_i \end{cases}$$

    that is orthogonal but not orthonormal:

    $$\left\langle \delta_{C_i}, \delta_{C_j} \right\rangle = \begin{cases} 0 & C_i \neq C_j \\ \frac{|C_i|}{|G|} & C_i = C_j \end{cases}$$

    - How do we relate the two bases?
    - To begin, fix C_i. Then

    $$\delta_{C_j}(g) = \sum_{V_i} \lambda_i \chi_{V_i}(g)$$

    - λ_i can be computed immediately using the inner product since the characters are orthonormal:

    $$\lambda_i = \left\langle \delta_{C_j}, \chi_{V_i} \right\rangle = \frac{1}{|G|} \sum_{g \in G} \delta_{C_j}(g)\overline{\chi_{V_i}(g)} = \frac{|C_j|\bar{\chi}_{V_i}(g)}{|G|}$$

        ■ You took $\lambda_i = \left\langle \delta_{C_j}, \bar{\chi}_{V_i} \right\rangle$; which one is correct??

    - But then

    $$\delta_{C_j}(g) = \frac{|C_j|}{|G|} \left(\sum_{V_i} \bar{\chi}_{V_i}(C_j)\chi_{V_i}(g) \right)$$

- It follows that we have two bases of $\mathbb{C}_{\mathrm{cl}}[G]$. These are given by

$$\frac{|G|}{|C_j|}\delta_{C_j} \qquad\qquad\qquad\qquad \chi_{V_i^*}$$

  where $i, j = 1, \ldots, k$.

- How do we convert between these two very natural bases of our space of functions? The change of basis matrix from left to right is the character table.

- Obviously, we have to do some scaling and take some duals, but it's not that bad and it fits the character table really well.

- This gives us some properties of the character table such as orthogonality.

- For example, **orthogonal** matrices convert between orthogonal bases; in the complex domain, such a matrix is **unitary**, i.e., for the character table U, $U\bar{U}^T = E$.

- Orthogonality relations that you can derive.

  1. We can show that

  $$\sum_{g \in G} \chi_1(g)\overline{\chi_2(g)} = \begin{cases} 0 & \chi_1 \neq \chi_2 \\ |G| & \chi_1 = \chi_2 \end{cases}$$

     - Use the unitary condition.

  2. We can show that

  $$\sum_{i=1}^{k} \chi_i(g_1)\overline{\chi_i(g_2)} = \begin{cases} 0 & g_1 \neq g_2 \\ \frac{|G|}{|C(g_1)|} & g_1 \sim g_2 \end{cases}$$

     - We literally just take the identity defining $\delta_{C_j}(g)$.

- **Isotypical component**: A representation that is equal to the direct sum of isomorphic irreducible representations. *Also known as* **isotypic component**.

  - Illustrative example: For $V = V_1^{n_1} \oplus \cdots \oplus V_k^{n_k}$, each $V_i^{n_i}$ is an isotypical component.

  - Think "iso" "typical" = "same" "type" (of component).

- Examples.

  1. Let $G \circlearrowright \mathbb{C}^2$ by $\rho(g) = E_2$. Thus, we can say that $\mathbb{C}^2 = V_1 \oplus V_1$, but we can't say this in any unique, canonical way, i.e., we can choose infinitely many V_1's and have the statement still be true, where V_1 is the trivial rep.

  2. We have $V_1^{n_1} = V^G = \{v \in V \mid gv = v \; \forall \, g \in G\}$. Look at what's invariant under the symmetry group, i.e., define

  $$P = \frac{1}{|G|}\sum g$$

     - All **invariant functions** come from averaging over the group!
     - Then $P^2 = P$ and $\operatorname{Im} P = V^G$.
     - Takeaway: We call each $V_i^{n_i}$ an **isotypical component**.
     - What's going on in this example??

  3. The permutational representation for S_n decomposes into the sum of the trivial and standard reps; there is only one decomposition this way. If we look at $V_1 \oplus V_{\mathrm{stand}}^2$, then our decomposition will depend on a choice of a plane.

- Reminder.

  - Last time, we chose an $f \in \mathbb{C}_{\mathrm{cl}}[G]$, a representation V, and then took $\sum f(g)g : V \to V$ so that then $\sum f(g)g \in \operatorname{Hom}_G(V, V)$.

- Moreover, we proved that if V is irreducible, then this endomorphism is equal to a scalar λ times the identity matrix via Schur's lemma.
- Computing λ:

$$\lambda = \frac{|G|}{d_V} \langle f, \chi_V^* \rangle$$

  ■ Hard to remember but easy to derive.
- Define $V = V_1^{n_1} \oplus \cdots \oplus V_k^{n_k}$ and $P_i : V \to V_i^{n_i}$.
- In particular, look at

$$P_i = \frac{d_V}{|G|} \sum_{g \in G} \chi_{V_i^*}(g) g$$

  ■ This averaging operator is consistent with what we had before.
- P_i acts on V_i by

$$\frac{d_{V_i}}{|G|} \frac{|G|}{d_{V_i}} \left\langle \chi_{V_i^*}, \chi_{V_i^*} \right\rangle = 1$$

- P_i acts on V_j by

$$\frac{d_{V_i}}{|G|} \frac{|G|}{d_{V_i}} \left\langle \chi_{V_i^*}, \chi_{V_j^*} \right\rangle = 0$$

- Take $V = V_1^{n_1} \oplus \cdots \oplus V_k^{n_k}$ and apply P_i. It follows by the above that it is exactly the projection on $V_i^{n_i}$.
- Thus, $P_1 + \cdots + P_k = 1$. $P_i^2 = P_i$. $P_i P_j = 0$. This is called a/the (which one??) **idempotent decompostion**.
- Example: Let $v \in V$. Then $v = P_1 v + \cdots + P_k v$.
- Additionally, we can take a function f that is invariant under the group...??

- We're done early.

- We will not start the Frobenius determinant today.

- We will start on next week's content then so we can begin thinking about it.

- **Associative algebra**: A vector space over a field F that is also a (not necessarily commutative) ring, where we have a unit 1 in the ring, addition, and multiplication. Scalar multiplication: $\lambda a = (\lambda \cdot 1) \cdot a$. Associativity condition: $(\lambda a)b = \lambda(ab)$. *Denoted by* $\boldsymbol{A}$.

  - We'll only discuss finite-dimensional algebras in this course.

- Examples:

  1. $\mathbb{R}$, $\mathbb{C}$ (an algebra over $\mathbb{R}$).
  2. $\mathbb{H}$, a 4d algebra over $\mathbb{R}$. The algebra of quaternions. $\mathbb{H} = \mathbb{R} + \mathbb{R}i + \mathbb{R}j + \mathbb{R}k$.
     - Hamilton's remarkable discovery: There is a 4D set of numbers that is not commutative but is still associative and helps describe rotation in 3D or 4D space.
     - Multiplication rules:

$$i^2 = j^2 = k^2 = -1 \qquad\qquad ijk = -1$$

     - We should spend part of our weekend reading a history of quaternions!
  3. $M_{n \times n}(F)$, the **matrix algebra**.
  4. $A_1 \oplus \cdots \oplus A_n$, the **direct sum** of algebras.
     - Addition and multiplication are done pairwise.
  5. $A_1 \otimes A_2$.

– We will not talk about this today, though!

- Let's go back; let G be a finite group and consider $\mathbb{C}[G]$, the set of functions on G.

    – This algebra has some basis $\bigoplus \mathbb{C}e_g$.
    – To get the algebra structure, we just need a rule for multiplying basis elements. In this case, we use $e_{g_1}e_{g_2} = e_{g_1 g_2}$.
    – This is the **algebra over $\mathbb{C}$ of dimension G**.
    – Theorem: $\mathbb{C}[G] \cong M_{d_1 \times d_1}(\mathbb{C}) \oplus \cdots \oplus M_{d_k \times d_k}(\mathbb{C})$.
        - We can prove this theorem from what we know: Schur's Lemma and complete reducability.
        - We'll discuss it for several consecutive times.
        - A similar result holds for *many* algebras (e.g., semisimple algebra), not just *group* algebras.

- HW1-2 will be graded later this week and handed back on Friday.

- In Etingof et al. (2011), we can find a lot of history of some of this stuff. The comments are interesting and entertaining.

4.4   Frobenius Determinant; Intro to Associative Algebras

10/20:

- Let $G = \{g_1, \ldots, g_n\}$.

- **Frobenius determinant**: The polynomial defined as follows. *Denoted by $\boldsymbol{F(x_{g_1}, \ldots, x_{g_n})}$. Given by*

$$F(x_{g_1}, \ldots, x_{g_n}) = \det |x_{g_i g_j}|$$

    – The Frobenius determinant is a homogeneous polynomial with integer coefficients of degree n.
    – $F(x_{g_1}, \ldots, x_{g_n}) \in \mathbb{Z}[x_{g_1}, \ldots, x_{g_n}]$.

- Theorem: There exist irreducible $P_1, \ldots, P_m \in \mathbb{Z}[x_{g_1}, \ldots, x_{g_n}]$ such that

$$F = P_1^{\deg P_1} \cdots P_k^{\deg P_k}$$

Moreover, $\chi_i(g) \approx \chi_g^{\deg P_i}$, where χ_g is the coefficient of P_i. (Is this last line correct??)

Proof. Let $\rho : G \to GL_n$ be the regular representation of G, and define $P_\rho = \sum \chi_{g_i} \rho(g_i)$. Then $P_\rho(x_{g_1}, \ldots, x_{g_n}) = \pm I(x_{g_1}, \ldots, x_{g_n})$.

We have that $P_\rho(e_{g_j}) = \sum x_{g_i} g_i e_{g_j} = \sum x_{g_i} e_{g_i g_j} = \sum x_{g_i g_j^{-1}} e_{g_i}$, so the matrix of P_ρ is $(x_{g_i g_j^{-1}})$ and thus has permuted columns and rows relative to the original matrix of which we took the Frobenius determinant.

Recall that $\mathbb{C}[G] \cong V_1^{d_1} \oplus \cdots \oplus V_k^{d_k}$. Additionally, the matrix of each V_i is $(\sum \chi_g g_i)$.

Understanding this?? $\square$

- **Group algebra**: The algebra A over a field F with one basis element e_i for each $g_i \in G$ and the multiplication law $e_i \cdot e_j = \sum_{i=1}^k \lambda_{ij}^k e_k$. *Denoted by $\boldsymbol{F[G]}$. Given by*

$$F[G] = \{a_{g_1} g_1 + \cdots + a_{g_n} g_n \mid a_i \in F\}$$

    – $A \cong F^n$.
    – Note that the notation here is well chosen; see the discussion of the notation $\mathbb{C}[G]$ from the 10/9 lecture.

- **Division algebra**: An algebra A such that for all nonzero $x \in A$, there exists a $y \in A$ such that $xy = 1$.

- **Field**: A commutative division algebra.

- Examples.

    1. $\mathbb{C}$ is a 2-dimensional algebra over $\mathbb{R}$.

    2. $\mathbb{H}$ is a 4-dimensional algebra over $\mathbb{R}$.

        – As discussed last time, the elements are of the form $q = a + bi + cj + dk$ where $i^2 = j^2 = k^2 = -1 = ijk$

        – Note that it follows that
        $$\bar{q} = a - bi - cj - dk$$

        – Hence,
        $$q\bar{q} = a^2 + b^2 + c^2 + d^2$$

        – Thus, we can define
        $$q^{-1} = \frac{q}{a^2 + b^2 + c^2 + d^2}$$

- We now prove some results of division algebras.

    1. If $F = \mathbb{C}$, then every finite-dimensional division algebra is $\mathbb{C}$.

        Proof. Let A be an arbitrary finite-dimensional division algebra over $\mathbb{C}$. Let $a \in A$, and let $L_a \in GL_n(A)$ send $a \mapsto [L_a x \mapsto ax]$.
        Then $\mathbb{C} \to M_{2 \times 2}(\mathbb{R})$ sends
        $$a + bi \mapsto L_{a+bi} = \begin{bmatrix} \alpha & -\beta \\ \beta & \alpha \end{bmatrix}$$

        Then $L_a L_b = L_{ab}$ and $L_a + L_b = L_{a^{-1}b}$, so L_a has eigenvalue λ, so $L_a x = ax = \lambda x$, so $a = \lambda \cdot 1$.
        What is going on here and how does this work?? $\qquad\square$

- Example of the above property.

    – $\mathbb{H} \to M_{4 \times 4}(\mathbb{R})$ sends $a + bi + cj + dk$ to ?? with determinant $(a^2 + b^2 + c^2 + c^2)^2$.

    – In general, the determinant of $A \to GL_n(A)$.

- Theorem 1: Over $\mathbb{R}$, there are exactly three division algebras: $\mathbb{R}$, $\mathbb{C}$, and $\mathbb{H}$.

- Theorem 2: Over $\mathbb{F}_q$ finite, every finite-dimensional division algebra is a field $\mathbb{F}_{q^n}$.

- **Representation** (of A): A module V over A equipped with a homomorphism of algebras $\rho : A \to M_{n \times n}(V)$.

- Observation:

    – If G is a group and F is a field, then the group algebra is $F[G] = \bigoplus_{i=1}^{n} F e_{g_i}$. Herein, we define $e_{g_i} e_{g_j} = e_{g_i g_j}$.

    – Modules over $F[G]$ are equivalent to G reps.

    – $F[G] \to M_{n \times n}(F)$ is equivalent to $G \to GL_n(F)$.

- **Morphism** (of A-modules): A map $f : M \to N$ such that...

    1. f is a module homomorphism;

    2. f respects the structure of the representations; explicitly, for every $g \in G$, $\rho_N(g) \circ f = f \circ \rho_M(g)$.

- **$\mathrm{Hom}_A(M, N)$**: The set of all morphisms of A-modules from M to N.

- Schur's Lemma for associative algebras: Let A be a finite-dimensional algebra over a field F, and let M_1, M_2 be simple A-modules. Then we have the following statements.

1. If $f : M_1 \to M_2$ is a nonzero morphism of A-modules, then f is isomorphic.

2. If M is simple, then $\text{Hom}_A(M, M)$ is a division algebra over F.

- Note that this version of Schur's Lemma implies that complete reducibility may fail for associative algebras. (why??)

- Theorem (Complete Reducibility): Let A be a finite-dimensional algebra such that $M_1 \subset M_2$. Then there exists N such that $M_2 = M_1 \oplus N$. Moreover, it follows that

$$A \cong M_{n_1}(D_1) \oplus \cdots \oplus M_{n_k}(D_k)$$

4.5   S Chapter 2: Character Theory

From Serre (1977).

Section 2.5: Number of Irreducible Representations

11/9:
- We now build up to a proof that the number of irreducible representations is *equal* to the number of conjugacy classes.

- Matching the Lemma and additional comment from Monday's class.

  Proposition 6. *Let f be a class function on G, and let $\rho : G \to GL(V)$ be a linear representation of G. Let ρ_f be the linear mapping of V into itself defined by*

  $$\rho_f = \sum_{t \in G} f(t)\rho_t$$

  If V is irreducible of degree n and character χ, then ρ_f is a homothety of ratio λ given by

  $$\lambda = \frac{1}{n} \sum_{t \in G} f(t)\chi(t) = \frac{g}{n}(f \mid \chi^*)$$

  Proof. See class.   □

- Denote by H the space of class functions on G.

  - Thus, for example, $\chi_1, \ldots, \chi_h \in H$.
  - Does this differ somehow from $\mathbb{C}_{\text{cl}}[G]$, which is also used in Serre (1977)??

- Matching the Theorem from Monday's class.

  Theorem 6. *The characters $\chi_1, \ldots, \chi_h$ form an orthonormal basis of H.*

  Proof. See class.   □

- **Class**: A subset of G consisting of the elements sts^{-1} for some $g \in G$ and all $s \in G$. *Also known as* **conjugacy class**.

- Matching the final result of the Theorem from Monday's class.

  Theorem 7. *The number of irreducible representations of G (up to isomorphism) is equal to the number of classes of G.*

  Proof. Essentially, Serre (1977) is just separating out the notion that class functions *are constant on conjugacy classes.*   □

- Matching the second orthogonality relation from the class of the Friday of Week 3, and with similarities to the consequence of the Theorem from Monday's class.

Proposition 7. *Let $s \in G$, and let $c(s)$ be the number of elements in the conjugacy class of s.*

(i) *We have*

$$\sum_{i=1}^{h} \chi_i(s)^* \chi_i(s) = \frac{g}{c(s)}$$

(ii) *For $t \in G$ not conjugate to s, we have*

$$\sum_{i=1}^{h} \chi_i(s)^* \chi_i(t) = 0$$

(iii) *For $s = 1$, we recover Corollary 2 to Proposition 5 as a special case of parts (i)-(ii).*

Proof. For each $s \in G$, define

$$f_s(t) = \begin{cases} 1 & t \sim s \\ 0 & t \nsim s \end{cases}$$

Notice that as defined, f_s is a class function. Thus, since the characters form a basis of H,

$$f_s = \sum_{i=1}^{h} (f_s \mid \chi_i) \chi_i$$

where

$$(f_s \mid \chi_i) = \frac{1}{g} \sum_{t \in G} f_s(t) \chi_i(t)^* = \frac{c(s)}{g} \chi_i(s)^*$$

Combining these two results, we obtain the following equivalent formulation of f_s.

$$f_s(t) = \frac{c(s)}{g} \sum_{i=1}^{h} \chi_i(s)^* \chi_i(t)$$

If we set $t = s$ in the above equation, we recover (ii). If we set $t \nsim s$ in the above equation, we recover (ii). $\qquad \square$

- Serre (1977) constructs Table 3.1.

  - Postulates trivial and alternating representations.
  - An interesting way to recover the standard θ: From Corollary 1 to Proposition 5, we have that $\chi_1 + \chi_2 + 2\theta = \chi_{\text{reg}} = (6, 0, 0)$.
  - Serre (1977) discusses the geometric foundations of the standard representation.

4.6   FH Chapter 2: Characters

From Fulton and Harris (2004).

Section 2.4: More Projection Formulas; More Consequences

- Again, Fulton and Harris (2004) take an unconventional tack: Instead of looking for an average of endomorphisms this time around, what linear combinations of endomorphisms are G-linear?

- Here's an answer to the question, in a form with which we're quite familiar at this point.

   Proposition 2.28. *Let $\alpha : G \to \mathbb{C}$ be any function on the group G, and for any representation V of G, set*

   $$\varphi_{\alpha,V} = \sum \alpha(g) \cdot g : V \to V$$

   Then $\varphi_{\alpha,V}$ is a homomorphism of G-modules for all V if and only if α is a class function.

   Proof. See class.   □

- Matching the Lemma, additional comment, and Theorem from Monday's class.

   Proposition 2.30. *The number of irreducible representations of G is equal to the number of conjugacy classes of G. Equivalently, their characters $\{\chi_V\}$ form an orthonormal basis for $\mathbb{C}_{cl}(G)$.*

   Proof. See class.   □

- At this point, we know all there is to know about the characters of a finite group.

- Alternate way to express Proposition 2.30 (and a lot of other things we've learned about representations of a finite group G): Use the **representation ring** of G!

- Definition of **representation ring** and **virtual representation**.

- The character induces a map $\chi : R(G) \to \mathbb{C}_{\mathrm{cl}}[G]$.

   - Analogy of Proposition 2.1: χ is a ring homomorphism.
   - A representation is determined by its characters: χ is injective.
   - Proposition 2.30: χ induces an isomorphism $\chi_{\mathbb{C}} : R(G) \otimes \mathbb{C} \to \mathbb{C}_{\mathrm{cl}}[G]$.

- **Virtual character**: An element of $\mathrm{Im}(\chi)$.

- Goes over Figure 4.1.

- A few more comments.
